A significant segment of the process is devoted to the removal of the feathers which have to be removed from the carcass, for example, by chaffing, plucking or by mechanical feathers plucking. Plucking of poultry is not a new art. Since prehistoric times, people have harvested feathers from birds that were killed in one way or another. People have tried for years to improve the feather removal operation and to make it more efficient and to try to achieve a better result in the elimination of feathers and in the elimination of bacterial infection. The operation of plucking feathers has developed over time, and the present day operation is well-developed. Typically, an operator physically plucks the feathers with his or her fingers. The operator will move his or her hands along the skin, separating the feathers and moving them to a storage bin or to the side. The operator will pluck the upper part of the feather, thus obtaining only the upper part of the feather and any attached part of the skin. The plucking of the feathers is very time consuming and labor intensive. U.S. Pat. No. 3,937,413, dated Feb. 10, 1976, and U.S. Pat. No. 4,037,668, dated July 19, 1977, both to Frederich, et al., describe machines for removing feathers from poultry. The machines use a flexible plucking belt that is trained about a pair of rollers to pluck the feathers from the bird. Each roller has flexible fingers that extend from the roller into a trough formed in the plucking belt. The flexible fingers pluck the feathers from the bird as the bird moves past the plucking belt. This type of operation removes the feathers from the bird with the full thickness of
